Abstract

We compute the one-loop lattice renormalization of the two-quark operators $\bar{\psi}\Gamma\psi$, where Γ denotes the generic Dirac matrix, for the lattice formulation of QCD using the overlap-Dirac operator.

We also study the renormalization of quark bilinears which are more extended and have better chiral properties.

Finally, we present improved estimates of these renormalization constants, coming from cactus resummation and from mean field perturbation theory.

Keywords: Lattice QCD, overlap-Dirac operator, fermionic currents, lattice renormalization, lattice perturbation theory.

I. INTRODUCTION

Recent developments in lattice QCD have shown that chiral symmetry can be realized on the lattice without fermion doubling (for recent reviews see e.g. Refs. [1,2]), circumventing the Nielsen-Ninomiya theorem [3]. This has been achieved by introducing an overlap-Dirac operator [4] derived from the overlap formulation of chiral fermions [5]. The simplest such example, for a massless fermion, is given by the Neuberger-Dirac operator [4]

$$D_N = \frac{1}{a} \rho \left[1 + X(X^\dagger X)^{-1/2} \right], \quad (1)$$

$$X = D_W - \frac{1}{a} \rho, \quad (2)$$

where D_W is the Wilson-Dirac operator (with the Wilson parameter r set to its standard value, $r = 1$)

$$D_W = \frac{1}{2} \left[\gamma_\mu (\nabla_\mu^* + \nabla_\mu) - a \nabla_\mu^* \nabla_\mu \right], \quad (3)$$

$$\nabla_\mu \psi(x) = \frac{1}{a} [U(x, \mu) \psi(x + a\hat{\mu}) - \psi(x)], \quad (4)$$

a is the lattice spacing and ρ is a real parameter subject to the constraint $0 < \rho < 2$. Nonperturbatively one expects $-m_c < \rho < 2$, where $m_c < 0$ is the critical mass associated with the Wilson-Dirac operator.

D_N satisfies the Ginsparg-Wilson relation [6]

$$\gamma_5 D + D \gamma_5 = a D \gamma_5 D, \quad (5)$$

which protects the quark masses from additive renormalization [4,7]. Lattice gauge theories with Ginsparg-Wilson fermions have been proved to be renormalizable to all orders of perturbation theory [8]. The Ginsparg-Wilson relation allows us to write, at finite lattice spacing, relations that are essentially equivalent to those holding in the low-energy phenomenology associated with chiral symmetry (see e.g. Refs. [9,10]). It indeed implies the existence of an exact chiral symmetry of the lattice action under the transformation [11]

$$\delta_\epsilon \psi(x) = \epsilon \gamma_5 (1 - aD) \psi(x), \quad \delta_\epsilon \bar{\psi}(x) = \bar{\psi}(x) \gamma_5 \epsilon, \quad (6)$$

which can be extended to the flavour non-singlet case¹. The axial anomaly then arises from the non-invariance of the fermion integral measure under flavour-singlet chiral transformations [11–16]. A lattice formulation of QCD satisfying the Ginsparg-Wilson relation

¹ Actually Ginsparg-Wilson fermions are invariant under a more general transformation

$$\delta_\epsilon \psi(x) = \epsilon \gamma_5 (1 - v a D) \psi(x), \quad \delta_\epsilon \bar{\psi}(x) = \bar{\psi}(x) [1 - (1 - v) a D] \gamma_5 \epsilon, \quad (7)$$

where v can be chosen arbitrarily. All these symmetries are essentially equivalent, leading to equivalent Ward identities [10].

overcomes the complications of the standard approach (e.g. Wilson fermions), where chiral symmetry is violated at the scale of the lattice spacing. The chiral symmetry ensures that the hadron masses are free of $O(a)$ discretization errors. Indeed their leading scaling corrections are $O(a^2)$. The important point is that lattice Dirac operators satisfying Eq. (5) are not affected by the Nielsen-Ninomiya theorem [3], thus they need not suffer from fermion doubling.

Indeed, D_N avoids fermion doubling. The locality properties of D_N in the presence of a gauge field are not obvious. D_N is not strictly local, but locality should be recovered in a more general sense, i.e. allowing an exponential decay of the kernel of D_N with a rate which scales with the lattice spacing and not with the physical quantities [17]. Thus, the Neuberger-Dirac operator seems to have all the right properties that a lattice Dirac operator should have in order to describe massless quarks. However, its complexity renders its numerical implementation very demanding. In this respect some progress has been achieved (see, e.g., Refs. [17–27]), and Monte Carlo simulations seem to be already feasible, at least in quenched approximation.

The matrix elements of the fermionic currents are employed to predict hadronic decay constants, electromagnetic and weak form factors, quark masses, etc. A knowledge of their lattice renormalization constants is necessary to relate the matrix elements computed using lattice simulations to the corresponding ones defined using continuous renormalization schemes in experimental data analysis. In this paper we compute, to one loop in perturbation theory, the renormalization constants of local bilinear quark operators $\bar{\psi}\Gamma\psi$, where Γ denotes the generic Dirac matrix, in the lattice formulation of QCD using the Neuberger-Dirac operator. We also extend our computation to quark bilinears which are more extended and have improved chiral properties. In view of the better chiral behaviour of the Neuberger-Dirac operator, we expect it to have a wider use in Monte Carlo studies of hadronic physics; such studies require knowledge of the above renormalization constants.

Perturbative computations are much more cumbersome than in the case of Wilson fermions, due to the more complicated structure of the Neuberger-Dirac operator [28–30]. One-loop calculations are already quite complicated, and require the use of symbolic manipulation packages. We have developed such a package in Mathematica. An example of one-loop calculation using the Neuberger-Dirac operator is reported in Ref. [29], where we computed the ratio $\Lambda_L/\Lambda_{\overline{MS}}$ between the Λ -parameters of the lattice formulation and of the $\overline{MS}$ renormalization scheme.

Nonperturbative methods to estimate the renormalization constants, such as those of Refs. [31–33] would in general be preferable to approximations based on perturbative calculations, due to their better controlled systematic errors ($O(a)$ against $O(g_0^n)$). However, perturbative estimates may still be quite useful. They indeed provide important consistency checks. Further, in those cases where nonperturbative methods are very costly to implement, as in the case of the Neuberger formulation of the Dirac operator, perturbative methods may remain the only source of quantitative information.

One could, of course, define exactly conserved vector and axial currents having $Z_A = Z_V = 1$, following Noether’s procedure, (i.e. performing variations of the action with respect to the non-singlet chiral transformations of Eq. (6)). However, these Noether currents are rather complicated extended objects, which might be cumbersome to use in actual simulations. Their expressions for the Neuberger-Dirac operator can be found in Ref. [10].

The paper is organized as follows: In Sec. II we report the one-loop calculations necessary for the evaluation of the lattice renormalizations of the two-quark operators. In Sec. III we improve the one-loop estimates by performing a resummation to all orders of a certain class of gauge invariant diagrams, dubbed “cactus” diagrams [34–36]. We also compare them with the results of other improvement recipes [37,38], such as the so-called tadpole improved perturbation theory.

II. ONE-LOOP LATTICE RENORMALIZATION OF THE TWO-QUARK OPERATORS

A. Formulation of the problem

The lattice regularization of QCD we consider is described by the action

$$S_L = \frac{1}{g_0^2} \sum_{x,\mu,\nu} \text{Tr} [1 - U_{\mu\nu}(x)] + \sum_{i=1}^{N_f} \sum_{x,y} \bar{\psi}_i(x) D_N(x,y) \psi_i(y). \quad (8)$$

where $U_{\mu\nu}(x)$ is the usual product of $SU(N)$ link variables $U_\mu(x)$ along the perimeter of a plaquette originating at x in the positive μ - ν directions, and N_f is the number of massless quark flavours.

The observables we study are bilinear quark operators of the form

$$O_i = \bar{\psi}(x) \Gamma_i \psi(x), \quad (9)$$

where Γ_i denotes generic Dirac matrices, i.e.

$$1, \gamma_5, \gamma_\mu, \gamma_\mu \gamma_5, \sigma_{\mu\nu} \gamma_5. \quad (10)$$

Specific bilinear operators are denoted according to their Lorentz group transformations: $S(x) \equiv \bar{\psi}(x) \psi(x)$, $P(x) \equiv \bar{\psi}(x) \gamma_5 \psi(x)$, $V_\mu(x) \equiv \bar{\psi}(x) \gamma_\mu \psi(x)$, $A_\mu(x) \equiv \bar{\psi}(x) \gamma_\mu \gamma_5 \psi(x)$, and $T_{\mu\nu}(x) \equiv \bar{\psi}(x) \sigma_{\mu\nu} \gamma_5 \psi(x)$. In the above definitions, flavour indices are left unspecified. Indeed, this is sufficient for our purpose, since one-loop calculations are unaffected.

The lattice renormalization constants Z_{O_i} of the operators O_i are defined once a renormalization scheme is given: we will consider the $\overline{\text{MS}}$ renormalization scheme. In order to simplify our calculations we work with zero quark mass. This is justified by the fact that renormalization constants in the $\overline{\text{MS}}$ scheme are independent of the fermionic mass.

We also introduce the following bilinear operators

$$S' \equiv \bar{\psi} \left(1 - \frac{1}{2} a D_N\right) \psi, \quad P' \equiv \bar{\psi} \gamma_5 \left(1 - \frac{1}{2} a D_N\right) \psi, \quad (11)$$

$$V'_\mu \equiv \bar{\psi} \gamma_\mu \left(1 - \frac{1}{2} a D_N\right) \psi, \quad A'_\mu \equiv \bar{\psi} \gamma_\mu \gamma_5 \left(1 - \frac{1}{2} a D_N\right) \psi, \quad (12)$$

which are extended, and local only in the more general sense holding for D_N . They are interesting since under the lattice chiral symmetry of Eq. (6) they transform as the corresponding operators in the continuum. Indeed one can easily check that

$$\delta_\epsilon S' = 2P' \epsilon, \quad \delta_\epsilon P' = 2S' \epsilon, \quad (13)$$

and under the non-singlet transformations

$$\delta_{\epsilon^a} \psi_i = \epsilon^a T_{ij}^a \gamma_5 (1 - aD) \psi_j, \quad \delta_{\epsilon^a} \bar{\psi}_i = \bar{\psi}_j \gamma_5 T_{ji}^a \epsilon^a, \quad (14)$$

the vector and axial currents V' and A' transform as

$$\delta_{\epsilon^b} V'^a = i f^{abc} \epsilon^b A'^c, \quad \delta_{\epsilon^b} A'^a = i f^{abc} \epsilon^b V'^c. \quad (15)$$

Using the corresponding Ward identities one can show that

$$Z_{S'} = Z_{P'}, \quad Z_{V'} = Z_{A'}. \quad (16)$$

We mention that, as pointed out in Refs. [9,10], the spontaneous breaking of the non-singlet chiral symmetry, Eq. (6), is related, for finite lattice spacing, to the vacuum expectation value (condensate) of the operator S' , i.e. it occurs if $\langle S' \rangle \neq 0$.

One can also prove that the renormalization constants of $O'_i \equiv \bar{\psi} \Gamma_i (1 - \frac{1}{2} a D_N) \psi$ coincide with those of the corresponding operators $O_i \equiv \bar{\psi} \Gamma_i \psi$. This can be seen from the path integral representation for Z_{O_i} : Upon fermionic integration, the factor of D_N in the definition of O'_i will cancel against a fermion propagator; there will remain another propagator which will give a vanishing contribution to Z_{O_i} , since it cannot develop any $\mathcal{O}(1/a)$ singularities (by virtue of chiral invariance, which forbids additive mass renormalization). Thus, using the relations Eq. (16), we also have that

$$Z_S = Z_P, \quad Z_V = Z_A. \quad (17)$$

Note that if one introduces the bare fermionic mass by writing the Dirac operator as in Ref. [39]

$$\left(1 - \frac{1}{2} a m_0\right) D_N + m_0, \quad (18)$$

then the renormalization of the fermionic mass is related to that of the operator $\bar{\psi} \left(1 - \frac{1}{2} a D_N\right) \psi$, denoted Z_S , by the relation

$$Z_m = Z_S^{-1}. \quad (19)$$

It is worth mentioning that the chiral symmetry of the Neuberger-Dirac operator ensures the absence of $\mathcal{O}(a)$ discretization errors only for the spectrum of the theory. In order to achieve the same property for generic matrix elements of local operators, one should employ improved operators [40]. This issue is discussed in Ref. [41] for bilinear operators constructed with Ginsparg-Wilson fermions; there it is shown that, for massless quarks, such an improvement can be achieved using the operators

$$O''_i \equiv \bar{\psi} \left(1 - \frac{1}{2} a D_N\right) \Gamma_i \left(1 - \frac{1}{2} a D_N\right) \psi. \quad (20)$$

Proceeding as before, one can prove that the renormalization constants of the operators O''_i are the same as those of the corresponding O_i .

The standard perturbative computation of the lattice renormalizations Z_{O_i} of the operators O_i requires the calculation of the two-quark one-particle irreducible function, $\Gamma(p)$, and

the two-quark one-particle irreducible functions $\Gamma_{O_i}(p)$ with an insertion of the operators O_i . In the massless case, the quark-field renormalization Z_ψ is obtained through the relation

$$\Gamma^{\overline{\text{MS}}}(p) = Z_\psi(a\mu)\Gamma^{\text{L}}(p) \quad (21)$$

where $\Gamma^{\text{L}}(p)$ is the two-quark function calculated on the lattice (in the limit $a \rightarrow 0$), and $\Gamma^{\overline{\text{MS}}}(p)$ is the $\overline{\text{MS}}$ -renormalized two-point function, which can be computed in the continuum. Indeed a simple calculation gives

$$\Gamma^{\overline{\text{MS}}}(p) = ip_\mu \gamma_\mu \left[1 + g^2 c_F \left(c \ln \frac{\mu^2}{p^2} + b^{\overline{\text{MS}}} \right) + O(g^4) \right], \quad (22)$$

where

$$c = \frac{\alpha}{16\pi^2}, \quad b^{\overline{\text{MS}}} = \frac{\alpha}{16\pi^2}, \quad (23)$$

and α is the gauge parameter. The renormalizations Z_{O_i} can be obtained by the equation

$$\Gamma_{O_i}^{\overline{\text{MS}}}(p) = Z_{O_i}(a\mu)Z_\psi(a\mu)\Gamma_{O_i}^{\text{L}}(p) \quad (24)$$

where $\Gamma_{O_i}^{\text{L}}(p)$ and $\Gamma_{O_i}^{\overline{\text{MS}}}(p)$ are the two-quark functions with an insertion of O_i calculated respectively on the lattice and in the continuum using the $\overline{\text{MS}}$ renormalization scheme. Setting

$$\Gamma_{O_i}^{\overline{\text{MS,L}}}(p) = \Gamma_i B_{O_i}^{\overline{\text{MS,L}}}(p), \quad (25)$$

one has

$$B_{O_i}^{\overline{\text{MS}}}(p) = 1 + g^2 c_F \left(c_{O_i} \ln \frac{\mu^2}{p^2} + b_{O_i}^{\overline{\text{MS}}} \right) + O(g^4), \quad (26)$$

where (setting $\alpha = 1$)

$$c_{S,P} = \frac{1}{4\pi^2}, \quad c_{V,A} = \frac{1}{16\pi^2}, \quad c_T = 0, \quad (27)$$

and

$$b_{S,P}^{\overline{\text{MS}}} = \frac{3}{8\pi^2}, \quad b_{V,A}^{\overline{\text{MS}}} = \frac{1}{16\pi^2}, \quad b_T^{\overline{\text{MS}}} = 0. \quad (28)$$

In the above formulae we have neglected terms proportional to $p_\mu p_\nu / p^2$; these are present also in the lattice expressions, and cancel out in the calculation of the renormalizations.

On the lattice one finds

$$\Gamma^{\text{L}}(p) = ip_\mu \gamma_\mu \left[1 + g^2 c_F \left(-c \ln a^2 p^2 + b^{\text{L}} \right) + O(g^4) \right], \quad (29)$$

and

$$B_{O_i}^{\text{L}}(p) = 1 + g^2 c_F \left(-c_{O_i} \ln a^2 p^2 + b_{O_i}^{\text{L}} \right) + O(g^4). \quad (30)$$

Using Eqs. (21) and (24), we obtain

$$Z_\psi = 1 + g^2 c_F \left(c \ln a^2 \mu^2 + b^{\overline{\text{MS}}} - b^{\text{L}} \right) + O(g^4), \quad (31)$$

$$Z_{O_i} = 1 + g^2 c_F \left[(c_{O_i} - c) \ln a^2 \mu^2 + b_{O_i}^{\overline{\text{MS}}} - b^{\overline{\text{MS}}} - b_{O_i}^{\text{L}} + b^{\text{L}} \right] + O(g^4), \quad (32)$$

Note that Z_{O_i} are independent of the gauge parameter α .

So, to compute Z_{O_i} we need to evaluate the constants b^{L} and $b_{O_i}^{\text{L}}$ by a one-loop perturbative calculation on the lattice. We have to expand the Neuberger-Dirac operator in powers of g_0 , and use the resulting vertices to construct the diagrams related to the one-particle irreducible functions $\Gamma^{\text{L}}(p)$ and $\Gamma_{O_i}^{\text{L}}(p)$. In the appendix we list the relevant formulae for our one-loop calculations.

B. Results and discussion

Two diagrams contribute to $\Gamma^{\text{L}}(p)$, shown in Figure 1; for $B_{O_i}^{\text{L}}(p)$, there is only one diagram to one-loop, shown in Figure 2. Given that the 4-point vertex contains a part with an internal momentum (k in Eq. (A9)), the corresponding part of the second diagram in Fig. 1 actually has the same connectivity as the first diagram.

FIGURES 1, 2. One-loop diagrams contributing to the functions $\Gamma^{\text{L}}(p)$ (Fig. 1), and $B_{O_i}^{\text{L}}(p)$ (Fig. 2). Wavy (solid) lines represent gluons (fermions); a cross is an insertion of the operator O_i .

The algebra involving lattice quantities was performed using a symbolic manipulation package which we have developed in Mathematica. For the purposes of the present work, this package was augmented to include the propagator and vertices of the overlap action.

We express our results in the form of Eqs. (29), (30). The parameters $b^L, b_{O_i}^L$ depend on ρ , but not on N or N_f .

To extract the p -dependence, we first isolate the divergent terms; these are responsible for the logarithms. There are only a few such terms, and in the pure gluonic case their values are well known. We can use these values also in diagrams with fermions, applying successive subtractions of the type:

$$\frac{1}{\bar{q}^2} = \frac{1}{\tilde{q}^2} + \left(\frac{1}{\bar{q}^2} - \frac{1}{\tilde{q}^2} \right) \quad (33)$$

where $\tilde{q}^2$ is the inverse fermionic propagator. All remaining terms now contain no divergences, and can be evaluated by Taylor expansion in ap .

At this stage, one is left with expressions which no longer contain p and must be numerically integrated over the loop momentum. Given the complicated form of the overlap vertices, these expressions turn out to be quite lengthy, containing a few hundred terms in the cases at hand.

The integration is done in momentum space over finite lattices; an extrapolation to infinite size is then performed, in the manner of Ref. [42]. We evaluated the integrals for a range of values of the parameter ρ , as presented in Table 1. For all values of ρ that we quote, lattice sizes $L \leq 128$ are sufficient to yield answers to at least 7 significant digits (the uncertainty coming from a systematic error in the extrapolation, which can be estimated quite accurately). As the endpoints of the perturbative domain of ρ are approached ($\rho \rightarrow 0, \rho \rightarrow 2$), some of the quantities we calculate require increasingly larger lattices, for similar accuracy; this is, of course, a reflection of the divergences in the propagator at these endpoints. Figure 3 shows the dependence of our results on ρ , for the whole range $0 < \rho < 2$.

A number of consistency checks, some of which are rather nontrivial, may be performed on our results. In particular:

- The logarithmic coefficients must equal those of the continuum.
- Terms proportional to $p_\mu p_\nu / p^2$, which appear in Z_V, Z_A , should match those of the continuum.
- $Z_V = Z_A, \quad Z_S = Z_P$.
- No $\mathcal{O}(p^0)$ terms must appear in $\Gamma^L(p)$, i. e. no additive mass renormalization, as required by chiral symmetry.

Our results fulfill all of the above requirements. The last one serves also to verify our estimates of the systematic errors coming from the extrapolation.

FIGURE 3. The coefficients $b^L(\rho)$, $b_{O_i}^L(\rho)$, as a function of the parameter ρ .

For quick reference, we write the one-loop values of $Z_\psi(\alpha = 1)$, Z_{O_i} at $\rho = 1$, as follows:

$$Z_\psi = 1 + g^2 c_F [(\ln a^2 \mu^2)/16\pi^2 - 0.231966] \quad (34)$$

$$Z_{S,P} = 1 + g^2 c_F [3(\ln a^2 \mu^2)/16\pi^2 + 0.204977] \quad (35)$$

$$Z_{A,V} = 1 + g^2 c_F [0.198206] \quad (36)$$

$$Z_T = 1 + g^2 c_F [-(\ln a^2 \mu^2)/16\pi^2 + 0.204392] \quad (37)$$

III. IMPROVED PERTURBATION THEORY

In order to improve the estimates coming from lattice perturbation theory, one may perform a resummation to all orders of the so-called “cactus” diagrams [34–36]. Briefly stated, these are gauge-invariant tadpole diagrams which become disconnected if any one of their vertices is removed. The original motivation of this procedure is the well known observation of “tadpole dominance” in lattice perturbation theory. In the following we refer to Ref. [34] for definitions and analytical results.

Since the contribution of standard tadpole diagrams is not gauge invariant, the class of gauge invariant diagrams we are considering needs further specification. By the Baker-Campbell-Hausdorff (BCH) formula, the product of link variables along the perimeter of a plaquette can be written as

$$\begin{aligned} U_{x,\mu\nu} &= e^{ig_0 A_{x,\mu}} e^{ig_0 A_{x+\mu,\nu}} e^{-ig_0 A_{x+\nu,\mu}} e^{-ig_0 A_{x,\nu}} \\ &= \exp \left\{ ig_0 (A_{x,\mu} + A_{x+\mu,\nu} - A_{x+\nu,\mu} - A_{x,\nu}) + \mathcal{O}(g_0^2) \right\} \\ &= \exp \left\{ ig_0 F_{x,\mu\nu}^{(1)} + ig_0^2 F_{x,\mu\nu}^{(2)} + \mathcal{O}(g_0^4) \right\} \end{aligned} \quad (38)$$

The diagrams that we propose to resum to all orders are the cactus diagrams made of vertices containing $F_{x,\mu\nu}^{(1)}$. Terms of this type come from the pure gluon part of the lattice action. These diagrams dress the transverse gluon propagator P_A leading to an improved propagator $P_A^{(I)}$, which is a multiple of the bare transverse one:

$$P_A^{(I)} = \frac{P_A}{1 - w(g_0)}, \quad (39)$$

where the factor $w(g_0)$ will depend on g_0 and N , but not on the momentum. The function $w(g_0)$ can be extracted by an appropriate algebraic equation that has been derived in Ref. [34] and that can be easily solved numerically; for $SU(3)$, $w(g_0)$ satisfies:

$$u e^{-u/3} \left[u^2/3 - 4u + 8 \right] = 2g_0^2, \quad u(g_0) \equiv \frac{g_0^2}{4(1 - w(g_0))}. \quad (40)$$

The vertices coming from the gluon part of the action, Eq. (8), get also dressed using a procedure similar to the one leading to Eq. (39) [34]. Vertices coming from the Neuberger-Dirac operator stay unchanged, since their definition contains no plaquettes on which to apply the linear BCH formula.

One can apply the resummation of cactus diagrams to the calculation of the renormalization of lattice operators. Approximate expressions are obtained by dressing the corresponding one-loop calculations. Applied to a number of cases of interest [34,35], this procedure yields remarkable improvements when compared with the available nonperturbative estimates. As regards numerical comparison with other improvement schemes, such as boosted perturbation theory [37,38], cactus resummation fares equally well on all the cases studied [36]. It is worth mentioning in passing that cactus resummation also affords us a systematic means of improving perturbation theory, by successively dressing higher loop diagrams.

Let us consider the renormalizations Z_V, Z_A of isovector fermionic currents, which are finite functions of the bare coupling g_0 . At one-loop order we have

$$Z_{V,A} = 1 + g_0^2 z_{V,A} + \dots, \quad (41)$$

where the constants z_V and z_A have been calculated in Sec.II. The cactus dressing of the above one-loop expressions can be simply obtained by using the dressed transverse gluon propagator, Eq. (39). We thus obtain the following approximate expressions

$$Z_{V,A} \approx 1 + g_0^2 \frac{z_{V,A}}{1 - w(g_0^2)} \quad (42)$$

Let us apply the above formula to the lattice $SU(3)$ gauge theory, for which $z_{V,A} = 0.26427$, at $g_0 = 1$ which is a typical value for Monte Carlo simulation. Since [34],

$$1 - w(g_0 = 1) = 0.749775, \quad (43)$$

we find $Z_{V,A}(\rho = 1) \simeq 1.35$

Other recipes of improvement have been proposed in the literature (see e.g. [38], and [43] for a review of them) that essentially consist in a better choice of the expansion parameter. Among them we mention the so-called tadpole improvement [38] (MFI) motivated by mean-field arguments, in which one scales the link variable with $u_0(g_0^2) \equiv \langle \frac{1}{N} \text{Tr } U_{x,\mu\nu} \rangle^{1/4}$ as measured in the Monte Carlo simulation. Accordingly one rescales the coupling constant: $g_0^2 \rightarrow g_{\text{mf}}^2 = g_0^2/u_0^4$. Thus, one obtains a mean-field improved expansion

$$Z_{V,A} = u_0 \left[1 + g_{\text{mf}}^2 \left(z_{V,A} + \frac{1}{12} \right) + O(g_{\text{mf}}^4) \right] \quad (44)$$

For example, for $SU(3)$ in the quenched approximation and at $g_0^2 = 1$ one finds $u_0 \simeq 0.878$ and $g_{\text{mf}}^2 \simeq 1.68$. Putting these number in Eq. (44) we obtain $Z_{V,A} \simeq 1.39$, which is in reasonable agreement with the estimate coming using the cactus resummation.

Acknowledgements: H. P. would like to acknowledge the warm hospitality extended to him by the Theory Group in Pisa during various stages of this work. H. P. and E.V. would like to thank L. Del Debbio for useful discussions.

APPENDIX A:

In order to perform the lattice perturbative calculation we must formally expand D_N in powers of g_0 . We list here the relevant expressions for the propagator and vertices, following Ref. [28].

Let us first write down the weak coupling expansion of the Wilson-Dirac operator D_W . This will be useful for constructing the relevant vertices of D_N . We write

$$X(q, p) = D_W(q, p) - \frac{1}{a} \rho = X_0(p)(2\pi)^4 \delta^4(q - p) + X_1(q, p) + X_2(q, p) + O(g_0^3), \quad (A1)$$

where

$$X_0(p) = \frac{i}{a} \sum_{\mu} \gamma_{\mu} \sin ap_{\mu} + \frac{1}{a} \sum_{\mu} (1 - \cos ap_{\mu}) - \frac{1}{a} \rho, \quad (A2)$$

$$\begin{aligned} X_1(q, p) &= g_0 \int d^4 k \delta(q - p - k) A_{\mu}(k) V_{1,\mu}(p + k/2), \\ V_{1,\mu}(q) &= i\gamma_{\mu} \cos aq_{\mu} + \sin aq_{\mu}, \end{aligned} \quad (A3)$$

$$X_2(q, p) = \frac{g_0^2}{2} \int \frac{d^4 k_1 d^4 k_2}{(2\pi)^4} \delta(q - p - k_1 - k_2) A_\mu(k_1) A_\mu(k_2) V_{2,\mu}(p + k_1/2 + k_2/2), \quad (\text{A4})$$

$$V_{2,\mu}(q) = -i\gamma_\mu a \sin a q_\mu + a \cos a q_\mu.$$

The Fourier transform of the Neuberger-Dirac operator takes the form

$$\frac{1}{\rho} D_N(q, p) = D_0(p) (2\pi)^4 \delta^4(q - p) + \Sigma(q, p). \quad (\text{A5})$$

$D_0(p)$ is the tree level inverse propagator:

$$D_0^{-1}(p) = \frac{-i \sum_\mu \gamma_\mu \sin a p_\mu}{2 [\omega(p) + b(p)]} + \frac{a}{2}, \quad (\text{A6})$$

where

$$\omega(p) = \frac{1}{a} \left(\sum_\mu \sin^2 a p_\mu + [\sum_\mu (1 - \cos a p_\mu) - \rho]^2 \right)^{1/2}, \quad (\text{A7})$$

$$b(p) = \frac{1}{a} \sum_\mu (1 - \cos a p_\mu) - \frac{1}{a} \rho. \quad (\text{A8})$$

The function $\Sigma(q, p)$ can be expanded in powers of g_0 as

$$\begin{aligned} a\Sigma(q, p) = & \frac{1}{\omega(p) + \omega(q)} \left[X_1(q, p) - \frac{1}{\omega(p)\omega(q)} X_0(p) X_1^\dagger(p, q) X_0(q) \right] \\ & + \frac{1}{\omega(p) + \omega(q)} \left[X_2(q, p) - \frac{1}{\omega(p)\omega(q)} X_0(p) X_2^\dagger(p, q) X_0(q) \right] \\ & + \int \frac{d^4 k}{(2\pi)^4} \frac{1}{\omega(p) + \omega(q)} \frac{1}{\omega(p) + \omega(k)} \frac{1}{\omega(q) + \omega(k)} \times \\ & \left[-X_0(p) X_1^\dagger(p, k) X_1(k, q) - X_1(p, k) X_0^\dagger(k) X_1(k, q) - X_1(p, k) X_1^\dagger(k, q) X_0(q) \right. \\ & \left. + \frac{\omega(p) + \omega(q) + \omega(k)}{\omega(p)\omega(q)\omega(k)} X_0(p) X_1^\dagger(p, k) X_0(k) X_1^\dagger(k, q) X_0(q) \right] + \dots \end{aligned} \quad (\text{A9})$$

From $\Sigma(q, p)$ one can read off the vertices necessary for the one-loop calculations presented in this paper.

TABLE I. Coefficients $b^L(\rho), b_{O_i}^L(\rho)$.
